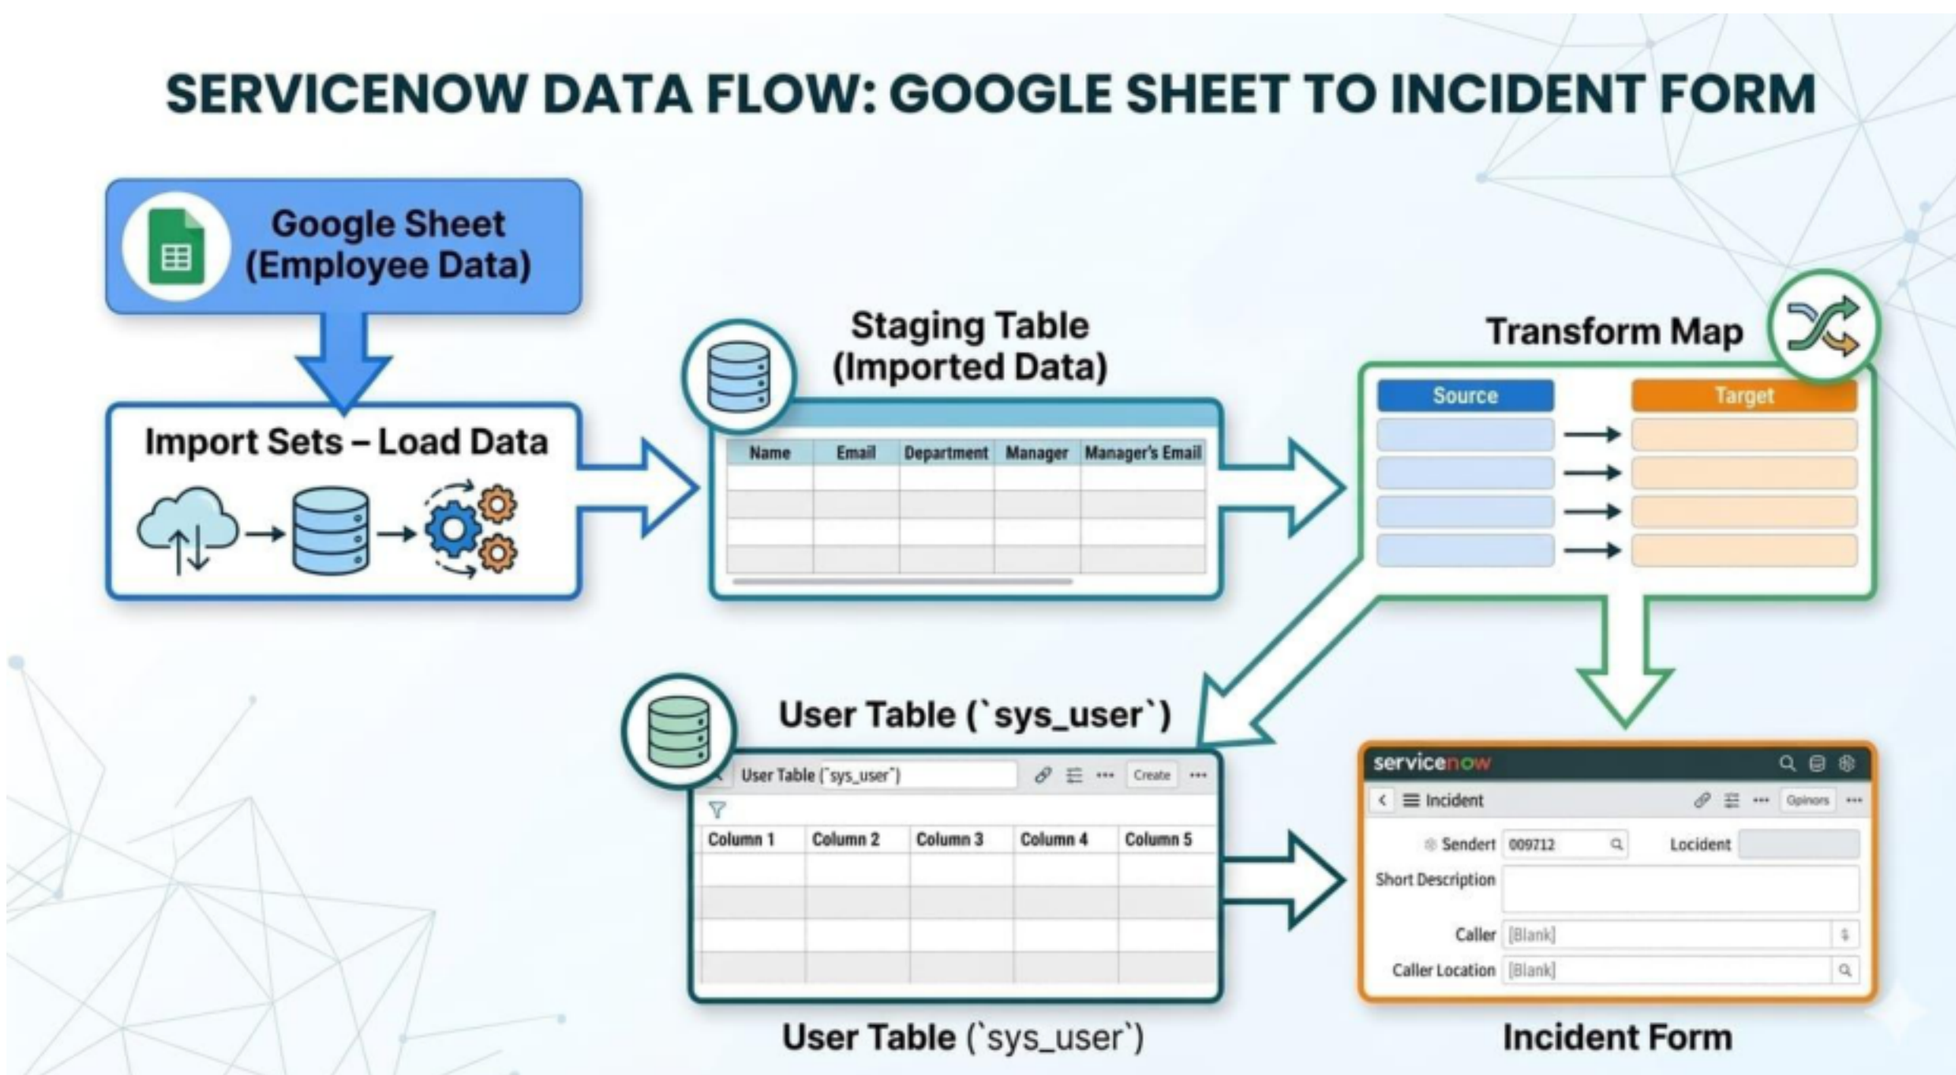
PROJECT DESIGN PHASE

TEAM ID	SWTID-2026-1705
PROJECT TITLE	AUTOMATING EMPLOYEE DATA

System Architecture



The system architecture explains how employee data flows through ServiceNow platform. Employee data is first prepared in Google Sheets.

This data is imported into ServiceNow using the Import Sets and Load Data module. The data is stored temporarily in a staging table.

Using Transform Maps, the data is transferred to the User table.

Finally, the incident form uses dot walking to automatically display employee details such as department, email, and manager.

Data Flow Design

The data flow design describes how information moves through the system.

Employee data is collected from an external source and uploaded into ServiceNow. The system processes the imported data and maps it to the appropriate fields in the user table. This ensures that the data is stored correctly and can be used in other modules like Incident Management.

Incident Form Design

The incident form is designed to automatically display employee-related information.

When an employee is selected in the Assigned To field, the system retrieves department, email, and manager details automatically using dot walking technique.

This reduces manual effort and ensures accurate information is available during incident creation.

Field Mapping Design

Field mapping is configured using Mapping Assist in Transform Maps. This process links fields from the source table to fields in the target table.
For example, employee name, email, department, and manager fields are mapped to corresponding fields in the user table. This ensures accurate data transfer during the transformation process.

Priority Configuration (Dictionary Override)

Dictionary override is used to customize field properties in specific tables. In this project design, dictionary override is used to configure the default priority value in the incident table. This helps categorize incidents properly and improves incident management workflow.
