PROJECT DEVELOPMENT PHASE

TEAM ID	SWTID-2026-1705
PROJECT TITLE	AUTOMATING EMPLOYEE DATA

System Setup

The development phase begins with setting up the required environment in the ServiceNow platform.

The platform is used to configure the modules required for employee data automation.

The developer logs into the ServiceNow instance and prepares the system for data import and configuration.

Necessary tables and modules such as Users table, Incident module, Import Sets, and Transform Maps are accessed during this phase.

~~Employee Data Preparation~~

In this step, employee data is prepared using Google Sheets. The data contains important fields such as employee name, email, department manager, and manager email. Sample employee records are created for testing and demonstration purposes. This data is organized properly so that it can be imported into the ServiceNow platform without errors.

Importing Employee Data

The prepared employee data is imported into ServiceNow using the Import Sets and Load Data module.

The data file is uploaded into the system and stored in a staging table.

This staging table temporarily holds the imported records before they are transferred to the target table.

This step ensures that the imported data can be reviewed and processed correctly.

Data Transformation

After importing the data, Transform Maps are configured to move the data from the staging table to the target table.

In this project, the target table is the Users table where employee records are stored permanently.

Mapping Assist is used to map fields from the source table to the corresponding fields in the target table.

This ensures that the employee name, email, department, and manager details are stored accurately in the system.

Incident Form Configuration

During development, the incident form is configured to retrieve employee-related information automatically.

When a user selects an employee in the Assigned To field, the system automatically displays department, email, and manager details using dot walking technique.

This feature helps reduce manual data entry and improves the efficiency of incident management.

~~Priority Configuration~~

The system also includes configuration for incident priority management.

Dictionary override can be used to customize the default value of the priority field in the incident table.

This allows the system to categorize incidents based on priority levels and ensures better incident handling and response time.

~~Testing and Verification~~

After completing the development steps, the system is tested to ensure that all functionalities work correctly.

The imported employee data is verified in the Users table. The incident form is also tested to confirm that department, email, and manager details are automatically populated when an employee is selected.

Any issues identified during testing are corrected before the final demonstration.

Final Implementation

After successful testing, the system is ready for final implementation.

The automated employee data system helps reduce manual effort and improves the overall efficiency of incident management in the organization.
